

EMBEDDING INFORMATION IN IMAGES

BACKGROUND

[0001] It is often useful to embed information within an image such that the information is not noticeable to a person viewing the image. There are practical applications for embedding information within the image. Security is one example. Embedding information representing the name of an employee and his or her social security number within the employee's identification photograph can not only add a level of security to the information but also can correlate the embedded information with the visual data. In many applications, it is also useful to reproduce an image with embedded information onto a printed, tangible medium for viewing, archiving, or transmission to others.

[0002] Certain embedding techniques feature the ability to store sizable amounts of information. However, these techniques have several requirements, including that the base image used during the embedding process be known, or at least approximated, for optimal information extraction. Thus these techniques are not "blind."

[0003] Robust and efficient blind decoding of images with embedded information is desirable.

SUMMARY

[0004] According to one aspect of the present invention, a method of processing a continuous tone image includes using a halftone screen to generate a bi-level bitmap; partitioning the contone image into an array of image blocks; halftoning the image blocks; using the bi-level bitmap to select some of the halftone image blocks; and modifying the selected halftone image blocks using code words, such that information contained in the code words is embedded in a halftone image.

[0005] According to another aspect of the present invention, a method of extracting embedded information in a halftone image includes accessing a bi-level bit map; partitioning the halftone image into a plurality of image blocks; using the bitmap to select at least some of the blocks; identifying a code word sequence in the selected blocks; and extracting the information from the code word sequence.

[0006] Other aspects and advantages of the present invention will become apparent from the following detailed description, taken in conjunction with the accompanying drawings, illustrating by way of example the principles of the present invention.

BRIEF DESCRIPTION OF THE DRAWINGS

[0007] Figure 1 is a functional block diagram of a computer system in accordance with an embodiment of the present invention.

[0008] Figure 2A is a flowchart of an information embedding method in accordance with an embodiment of the present invention.

[0009] Figure 2B is a flowchart of an information extraction method in accordance with an embodiment of the present invention.

[0010] Figure 3 is a flowchart of an encoder in accordance with an embodiment of the present invention.

[0011] Figure 4 is a flowchart of a decoder in accordance with an embodiment of the present invention.

[0012] Figure 5 is an illustration of a machine in accordance with an embodiment of the present invention.

DETAILED DESCRIPTION

[0013] As shown in the drawings for purposes of illustration, the present invention is embodied in a method of processing a continuous tone image. The method includes using a halftone screen to generate a bi-level bitmap; partitioning the contone image into an array of image blocks; halftoning the image blocks; using the bi-level bitmap to select some of the halftone image blocks; and modifying the selected halftone image blocks using code words, such that information contained in the code words is embedded in a halftone image. The information may be embedded at a rate that is linked to a graylevel of a contone patch. The bitmap may be produced by halftoning the constant patch of the graylevel. The graylevel is determined by a coding rate.

[0014] The present invention is also embodied in a method of extracting embedded information in a halftone image. The method includes accessing a bi-level bit

map; partitioning the halftone image into a plurality of image blocks; using the bitmap to select at least some of the blocks; identifying a code word sequence in the selected blocks; and extracting the information from the code word sequence.

[0015] The information embedding can be performed by an encoder, and the information extraction can be performed by a decoder. The decoding is blind, in that the base image used during the embedding is not needed to extract the embedded information.

[0016] The decoding is robust. The embedded information can be extracted from an image that went through a printer-scanner pipeline (e.g., the image with the embedded information was halftoned and printed, and the printed image was scanned).

[0017] Referring to Figure 1, computer system 100 executes encoding process 114, which embeds information into an input image, stores the resultant image in storage 110, and/or transmits the resultant image via network 180. Network 180 may be, for example, a local area network, wide area network, or a distributed network such as the Internet. Transmission may be followed by remote file storage of the image, or sending the image (e.g., via e-mail) to a different system.

[0018] The resultant image with the embedded information can be output by a printer 120. Printer 120 may be, for example, a laser printer or an ink jet printer.

[0019] The printed image may be converted to a digital image by a scanner 140. The scanner 140 and the printer 120 form a printer-scanner pipeline 160.

[0020] Computer system 100 or another system may execute decoding process 116 to extract the information embedded in the digital image. Encoding process 114 may be separate from the decoding process 116, encoding process 114 may be executed by one or more systems, and decoding process 116 may be executed by one or more systems which are different or the same as the system or systems that execute the encoding process 114.

[0021] Decoding process 116 may receive the digital image directly from the scanner 140. Instead of retrieving the digital image directly from the scanner 140, the image may be retrieved from storage 110, or received via network 180. In general, the source of the image to be decoded is not limiting to the present invention.

[0022] Encoding process 114 and decoding process 116 are preferably implemented as software or firmware, but in alternative embodiments may be implemented in hardware, e.g., in custom ASICs or dedicated processors.

[0023] Figure 2A provides further detail of the encoding process 116 executed by encoder 220. As can be seen, a continuous tone image 200 is input into encoder 220. Encoder 220 also accepts input of data 210, which will be embedded into image 200. Encoder 220 further has stored, or accepts, an encoding rate value, which determines the embedding rate of data 210 within input image 200. Output 230 of encoder 220 is a modified version of input image 200 (i.e., modified image data) that can be viewed with appropriate viewing software, such as that provided by default with major computer operating systems printed, or otherwise displayed. Output 230 may also be stored in local storage and/or on a remote file server, or transmitted to one or more other systems over a network, via e-mail for example.

[0024] The decoding process is shown in Figure 2B. As can be seen, an input image 250 is supplied to decoder 260. Input image 250 can be obtained from a scanner, local storage, or a network, or from any other source. Input image 250 is fed into decoder 260, where it is analyzed, and the information embedded in the input image 250 extracted and produced as data 270. In one embodiment, decoder 260 also produces the original image used to create the modified image during a previous encoding process.

[0025] Figure 3 presents a more detailed view of one embodiment of encoder 220, including a halftone gray level bitmap generator, halftoning and error diffusion processes, and information embedding logic, as will be explained.

[0026] A halftone gray level parameter 300, which is indicative of a selected encoding rate for the embedded information, is used to generate a halftone bitmap 310 consisting of binary data, composed of zeros and ones. This bitmap generation may be performed by any suitable halftoning technique, such as block error diffusion or halftone screening (dithering), for example. See J. Allebach and Q. Lin, "FM screen design using the DBS algorithm", Proceedings of 3rd IEEE International Conference on Image Processing, vol. 1, pp. 549-552, Sept. 1996. In one embodiment, such a halftone bitmap 310 is composed of aperiodic data and designed to achieve the highest possible spatial frequency. Such a bitmap composition is one way to minimize the visual impact of the embedded information.

[0027] In an alternative embodiment, halftone bitmap 310 can be retrieved using halftone gray level parameter 300 as an index into a table of pre-generated binary bitmaps. The zeros and ones in binary halftone bitmap 310 indicate where information will be embedded. The dimensions of halftone bitmap 310 are application or user selectable, and need not have any relation to the dimensions of the input image 250.

[0028] The value of halftone gray level parameter 300 is based on the combination of the desired modified image quality level and the amount of information to be embedded in the image. In general, information capacity of the modified image may be traded for image quality in a smooth manner by appropriate adjustment of the value of halftone gray level parameter 300. A smaller value of halftone gray level parameter 300 results in a lower information embedding rate and therefore higher visual quality of the modified image, while a larger value of halftone gray level parameter 300 results in a higher information embedding rate, and a reduced visual quality of the modified image. For a particular application, such as a corporate ID photo, a particular value of halftone gray level parameter 300 may be selected, and then set as a constant within encoder 220. For other applications, the value of halftone gray level parameter 300 may be varied interactively until a satisfactory blend of information embedding rate and image quality is achieved.

[0029] Image partitioner 315 partitions original image 200 into a plurality of sub-matrices (or sub-images). For example, if original image 200 is an $M \times N$ pixel image, it may be partitioned into a regular array of $O \times K \times K$ pixel sub-matrices, where $O = M \times N / (K \times K)$. Optionally, one or more original image sub-matrices may be reserved for fiducial marks, and would be separately assembled into encoded halftone image 390. A fiducial mark pattern could be used to track one or more reference locations and local deformation across the resulting graphical bar code, for example, in a manner described in U.S. Patent Application No. 20020186884 by Doron Shaked et al., published Dec. 12, 2002 and entitled "Fiducial Mark Patterns for Graphical Bar Codes."

[0030] The unprocessed sub-matrices ($x(m)$) of original image 200 are optionally passed through difference stage 330, which incorporates diffused errors $t(m)$ into the original image blocks $x(m)$ to produce modified image blocks $u(m)$. The modified image blocks $u(m)$ are quantized at a thresholding stage 340 to generate blocks $o(m)$, which are halftone versions of $x(m)$. In particular, at the threshold stage 102, each modified image block $u(m)$ is assigned a respective representative quantized block that is

selected from a subset of possible representative halftone blocks (or regions). For example, in one embodiment, each modified image block $u(m)$ may be represented either by an all-bright pixel block (i.e., a block with all pixels equal to maximum intensity) or an all-dark pixel block (i.e., a block with all pixels equal to lowest intensity).

[0031] Code words are generated by a code word sequence generator 360 from embedded data 210. In one embodiment, this merely involves using embedded data 210 directly, bit by bit. In another embodiment, error checking coding is added to embedded data 210 first, before being converted to code words. In yet another embodiment, data 210 is compressed before being translated into code words by a code word sequence generator 360. The code word sequence generator 360 utilizes the incoming data to produce graphical symbols which correspond to the code words. At logic stage 350, when a bit from halftone bitmap 310 corresponding to the spatial location of halftone image data $o(m)$ is $b(m)=1$, then a symbol corresponding to a code word is generated and the output is set to that symbol. More than one symbol may be used to represent a single code word as long as the code word is uniquely encodable from the symbol alone. The output from logic stage 350 is assembled into encoded halftone image 390, which corresponds to output 230.

[0032] Halftone bitmap 310 need not be the same size or larger than input image 200. Halftone bitmap 310 may in fact typically be smaller than input image 200, and as it is traversed during logic stage 350, when an edge of the bitmap is reached, will simply wrap back to the start of the opposite edge, akin to a tiling process.

[0033] In one embodiment, logic stage 350 may also contain additional logic that causes the test of $b(m)$ to be skipped when the input block $x(m)$ meets certain requirements, such as meeting certain minimum or maximum intensity thresholds, whereby the modified input image block is passed through to the output of logic stage 350. This may be done to improve the visual quality of the resultant encoded halftone image, as well as to reduce the accumulation of quantization errors in the resultant halftone image which occur when the code word block symbols are significantly different from the modified input image blocks in terms of average intensity value.

[0034] Optionally, errors introduced by logic stage 350 into the halftone image 390 as a result of the information embedding process are fed back via computer error computation stage 380 to shape error filter 320 such that the error $t(m)$ can be diffused among the as yet unprocessed, unreserved sub-matrices. This error diffusion

assists in improving the image quality of the halftone image 390 containing the embedded information, but in some applications, such error diffusion will not be necessary.

[0035] At error computation stage 380, quantization errors $e(m)$ are computed based upon differences between the blocks $u(m)$ of the modified image and the corresponding block output from logic stage 350. The quantization errors $e(m)$ are filtered by a linear shape error filter 320 to produce the diffused errors $t(m)$. In one embodiment, the linear error filter 320 has matrix valued coefficients and operates on the quantization error sequence $e(m)$ to produce the feedback signal sequence $t(m)$ according to:

$$t(m) = \sum_{k \in S} \tilde{h}(k) e(m - k) \quad (1)$$

where $\tilde{h}(\cdot)$ is an $N^2 \times N^2$ matrix-valued sequence and S is the filter support. The shape error filter 320 preferably is designed so that the diffused error is invariant to the specific message code word bit pattern at a given block. In the illustrated embodiment, the shape error filter 320 is configured to diffuse the average error. Additional details regarding the block error diffusion process may be obtained from U.S. Patent Application No.

2003/0038181, by the inventor, and entitled "System and Method for Embedding Information within a Printed Image Using Block Error Diffusion Halftoning," which is incorporated herein by reference. Additional details can also be found in N. Damera-Venkata and B. L. Evans, "FM Halftoning Via Block Error Diffusion," Proc. IEEE International Conference on Image Processing, vol. II, pp. 1081-1084, Thessaloniki, Greece (2001).

[0036] As an example, if a 1x1 block size is used by image partitioner 315 then the encoding process is tantamount to performing normal error diffusion. In other words, at the locations where $b(m)=1$, the output is determined directly by the code word 360. If a code word with a value of 1 is used then the output is set to 1. If a code word with a value of 0 is used then it is set to 0. The error between the past-error modified input and the output is then diffused. The halftone bitmap 310 thus acts as a threshold modulation matrix. However, at the embedding locations the information may be embedded at a lower resolution (using 2x2 blocks, for example) and the rest of the locations may be halftoned at a higher resolution (with 1x1 blocks, for example). This improves image quality and increases the average resolution above the typical bound for decodability.

[0037] Figure 4 presents a more detailed view of decoder 260. In general, decoder 260 includes a pre-processing stage 400, an alignment stage 410, a geometric correction stage 420, a code word extraction stage 430, an optional probabilistic analysis stage 440, and a code word decoding and output stage 480. The code word decoding and output stage 480 produces decoded data 270.

[0038] During the pre-processing stage 400, an input modified image is analyzed to locate the position of embedded information, and regions not containing information may be cropped and trimmed from input 250, e.g., in a manner described in U.S. Patent Application 20020196979 by Jonathan Yen et al., published Dec. 26, 2002 and entitled “Automatically Extracting Graphical Bar Codes.”

[0039] During the alignment stage 410, fiducial marks are detected in the pre-processed image. The configuration of the detected fiducial marks indicates the type of global deformations that might have been introduced into the graphical bar code during transmission of the input image, e.g. photocopying of the originally printed modified image, followed by scanning to produce input image 250. These global deformations (e.g., translational, rotational, affine and skew distortions) may be corrected by geometric correction stage 420, in a manner described in assignee’s U.S. Patent No.6,606,421 by Doron Shaked et al., issued April 12, 2003 and entitled “Geometric Deformation Correction Method and System for Dot Pattern Images.”

[0040] Once an aligned, geometrically corrected image is produced, it is processed through code word extraction stage 430. Halftone decoder 430 also accepts input from binary halftone bitmap 450. Binary halftone bitmap is generated at the same encoding rate used to embed the information during the encoding process for the image being processed. The encoding rate, which is determined by the selected value of the halftone gray level parameter 460, can either be a constant based on the type of image being processed (e.g. driver license pictures might use a predetermined encoding rate), or dynamically determined using any one of a variety of different possible methods. For example, particular image data may be included in a predetermined portion of the input image (e.g. a one dimensional barcode), where such data is a code indicating the value of the gray level parameter 460 to use. An alternate method includes an heuristic process whereby the method is iterated over a range of values of the gray level parameter 460 until a certain data signature is found in the decoded data, at which point the value of the gray level parameter 460 used to ascertain that signature is used to decode the rest of the

image. As another example, a fixed encoding rate is used for a particular portion of each image, wherein that portion contains embedded information that can be easily decoded since the encoding rate for that portion is known. Of course, other known methods of determining codes, signatures, and ciphers can be used as well.

[0041] As with the encoding process, logic stage 350 uses the binary bitmap 450 to determine where in an image embedded information is stored. The input image is partitioned into sub-matrices. The sub-matrix block size may either be a constant based on the application, or determined dynamically via methods similar to those described for determination of the value of halftone gray level 460.

[0042] In code word extraction stage 430, each relative bit of binary bitmap 450 is tested to see if it is a data indicator bit (e.g. value of 1) or an image indicator bit (e.g. value of 0). If it is an image indicator bit, the related sub-matrix of the aligned and corrected input image 250 is ignored or used to reconstruct the image (431); if it is a data indicator bit, then the image sub-matrix is passed to probabilistic analysis stage 440. In one embodiment, code word extraction stage 430 may also contain additional logic that causes the test of $b(m)$ from bitmap 450 to be skipped when the input block meets certain requirements, such as meeting certain minimum or maximum intensity thresholds, whereby the modified input image block is simply ignored as it is known to not be a data block.

[0043] During the probabilistic analysis stage 440, in one embodiment, probability models are applied to the extracted pixel values obtained from the aligned and geometrically corrected image to produce a set of probability parameters. The probability parameters may be used during the code word decoding stage 480 to select the most likely sequence of graphical code words that corresponds to the graphical code word sequence that originally was encoded into original image 250, e.g., in a manner described in U.S. Patent Application 20030047612 by Doron Shaked et al., published on March 13, 2003 and entitled "Generating and Decoding Graphical Bar Codes." The selected graphical code word sequence is translated into an encoded message that is decoded into decoded data 270 by the code word decoding stage 480. Error correction codes in the data can be used to ensure accuracy of the decoded data.

[0044] Reference is now made to Figure 5. A machine 510 includes a processor 512 and memory 514. The machine 510 may be a personal computer, wherein the processor 512 is general purpose processor. A program 516, when executed, causes

the processor 512 to perform any of the methods described above. The program 516 can be stored in “articles” such as the memory 514. During distribution, the program 516 can be stored in articles such as external removable media (e.g., optical discs) 518, etc.

[0045] The machine 510 may include a print engine, and the processor 512 and memory 514 are used to embed information in a halftone image. The machine 510 may include a scan engine, and the processor 512 and memory are used to extract information from a captured digital image and output both the captured image and the extracted information.

[0046] The encoding and decoding can be performed with any size input image (i.e. an image of any arbitrary dimension). Variable resolution encoding allows for overall greater image quality.

[0047] While the embodiments disclosed above relate to grayscale images, color images can be used instead of grayscale images, allowing for separately encoded information in each color component or embedding information in just one color component.

[0048] Although specific embodiments of the present invention have been described and illustrated, the present invention is not limited to the specific forms or arrangements of parts so described and illustrated. Instead, the present invention is construed according to the following claims.
